Summary of American Heart Association Diet and Lifestyle Recommendations Revision 2006

Alice H. Lichtenstein, Lawrence J. Appel, Michael Brands, Mercedes Carnethon, Stephen Daniels, Harold A. Franch, Barry Franklin, Penny Kris-Etherton, William S. Harris, Barbara Howard, Njeri Karanja, Michael Lefevre, Lawrence Rudel, Frank Sacks, Linda Van Horn, Mary Winston, Judith Wylie-Rosett

This article summarizes the recent American Heart Association (AHA) Science Statement, Diet and Lifestyle Recommendations, published in Circulation in the July 4, 2006 issue. Improving diet and lifestyle recommendations is a critical component of the AHA’s strategy for cardiovascular disease risk reduction in the general population. Specific goals are to consume an overall healthy diet; aim for a healthy body weight; aim for recommended levels of low-density lipoprotein cholesterol, high-density lipoprotein cholesterol, and triglycerides; aim for normal blood pressure; aim for a normal blood glucose level; be physically active; and avoid use of and exposure to tobacco products. The recommendations are to balance caloric intake and physical activity to achieve and maintain a healthy body weight; consume a diet rich in vegetables and fruits; choose fish, especially oily fish, at least twice a week; limit intake of saturated fat to <7% of energy, trans fat to <1% of energy, and cholesterol to <300 mg/d by choosing lean meats and vegetable alternatives, fat-free (skim) or low-fat (1% fat) dairy products and minimize intake of partially hydrogenated fats; minimize intake of beverages and foods with added sugars; choose and prepare foods with little or no salt; if you consume alcohol, do so in moderation; and when you eat food prepared outside of the home, follow these Diet and Lifestyle Recommendations. By adhering to these diet and lifestyle recommendations, the risk of developing cardiovascular disease can be substantially reduced, which means the leading cause of morbidity and mortality in the United States.

Improving diet and lifestyle is a critical component of the AHA strategy to prevent cardiovascular disease (CVD). The 2006 AHA Diet and Lifestyle Recommendations were designed to meet this objective and are one component of a comprehensive plan for cardiovascular risk reduction. The recommendations are appropriate for the general public, including adults and children over 2 years of age. Separate AHA dietary recommendations specifically addressing the special needs of growing children have recently been published.

Public Health and Clinical Application of AHA Diet and Lifestyle Recommendations

Public Health Recommendations

Maintaining a healthy diet and lifestyle offers the greatest potential of all known approaches to reduce CVD risk in the general public. This is still true in spite of major advances in clinical medicine. The recommendations contained in the document provide a foundation for a public health approach to CVD risk reduction through healthy eating habits and other lifestyle factors.

Clinical Recommendations

The recommendations can be applied to the clinical management of patients with or at risk for CVD. For certain patients at higher risk, the recommendations may have to be intensified. Although great advances have been made in prevention and treatment of CVD through drug therapies and procedures, diet and lifestyle therapies remain the foundation of clinical intervention for prevention. Unfortunately, the latter are commonly neglected, to the detriment of patients.

Goals

The AHA Diet and Lifestyle Goals are intended to reduce CVD risk (Table 1). They provide guidance for adults and children over the age of 2 years.

Consume an Overall Healthy Diet

Healthy dietary patterns are associated with a substantially reduced risk of CVD, CVD risk factors, and noncardiovascular diseases. An emphasis on the whole diet is appropriate to ensure nutrient adequacy and energy balance. The AHA recommends that individuals consume a variety of fruits, vegetables, and grain products, especially whole grains; choose fat-free and low-fat dairy products, legumes, poultry, and lean meats; and eat fish, preferably oily fish, at least twice a week.
Aim for a Healthy Body Weight
Obesity is an independent risk factor for CVD. Excess body weight adversely affects CVD risk factors (eg, increasing low-density lipoprotein [LDL] cholesterol levels, triglyceride levels, blood pressure [BP], and blood glucose levels, and reducing high-density lipoprotein [HDL] cholesterol levels) and increases the risk of developing coronary heart disease (CHD), heart failure, stroke, and cardiac arrhythmias. It is important to intensify efforts in the general population to help individuals avoid inappropriate weight gain during childhood and subsequent weight gain during adult years.

Aim for a Desirable Lipid Profile
LDL is the major cholesterol-carrying lipoprotein particle in plasma. Its concentrations are most closely associated with risk of developing CVD. The strongest dietary determinants of elevated LDL cholesterol concentrations are dietary saturated fatty acid and trans fatty acid intakes. To a lesser extent, dietary cholesterol and excess body weight are positively related to levels of LDL cholesterol. The concentration of HDL cholesterol is inversely associated with CVD risk. This association is thought to be mediated by a constellation of events collectively referred to as reverse cholesterol transport. Determinants of high triglycerides are mainly the extent, dietary cholesterol and excess body weight are positively related to levels of LDL cholesterol. The major dietary factors adversely affecting HDL cholesterol levels include very low-fat diets (<15% energy as fat) and excess body weight.

Aim for a Normal Blood Pressure
A normal BP is a systolic BP \( \leq 120 \text{ mm Hg} \) and a diastolic BP \( \leq 80 \text{ mm Hg} \). BP is a strong, consistent, continuous, independent, and etiologically relevant risk factor for cardiovascular-renal disease. Dietary factors known to lower BP are reduced salt intake, caloric deficit to induce weight loss, moderation of excess alcohol consumption, increased potassium intake, and consumption of an overall healthy diet consistent with the recommendations in this document.

Aim for a Normal Blood Glucose Level
A normal fasting glucose level is \( \leq 100 \text{ mg/dL} \), whereas diabetes is defined by a fasting glucose level \( \geq 126 \text{ mg/dL} \). Hyperglycemia and the often-associated insulin resistance are related to numerous cardiovascular complications, including CHD, stroke, peripheral vascular disease, cardiomyopathy, and heart failure. Reducing caloric intake and increasing physical activity to achieve even a modest weight loss can delay the onset of insulin resistance and improve glucose control once it is established.

Be Physically Active
Regular physical activity is essential for maintaining physical and cardiovascular fitness, maintaining healthy weight, and sustaining weight loss once achieved. Physical activity improves cardiovascular risk factors and lowers the risk of developing other chronic diseases.

Avoid Use of and Exposure to Tobacco Products
On the basis of the overwhelming evidence for the adverse effects of tobacco products and secondary exposure to tobacco smoke on CVD, as well as cancer and other serious illness, the AHA strongly and unequivocally endorses efforts to eliminate the use of tobacco products and minimize exposure to second-hand smoke. Concern about weight gain should not be a reason for continued use of tobacco products.

AHA Diet and Lifestyle Recommendations
These recommendations are intentionally presented in a manner that allows maximal flexibility in their implementation (Table 2). They are not presented as a “diet plan,” per se, but rather a lifestyle prescription to promote cardiovascular health. Practical approaches for implementing these recommendations are presented in Table 3.

Balance Calorie Intake and Physical Activity to Achieve or Maintain a Healthy Body Weight
To avoid weight gain after childhood, individuals must control calorie intake so that energy balance is achieved—that is, energy intake matches energy expenditure. To control calorie intake, individuals should increase their awareness of the calorie content of foods and beverages per portion consumed. Regular daily physical activity has been shown to be particularly effective in maintaining weight loss once achieved. The AHA recommends that all adults accumulate \( \geq 30 \) minutes of physical activity most days of the week.
Consume a Diet Rich in Vegetables and Fruits
In longitudinal observation studies, persons who regularly consume rich in vegetables and fruit diets are at a lower risk of developing cardiovascular disease, particularly stroke. Most vegetables and fruits are rich in nutrients, low in calories, and high in fiber. Vegetables and fruits that are deeply colored throughout (e.g., spinach, carrots, peaches, berries) should be emphasized. Techniques that preserve nutrient and fiber content without adding unnecessary calories, saturated or trans fat, sugar, and salt are recommended (Table 3). Fruit juice is not equivalent to the whole fruit in fiber content and perhaps satiety value and should not be emphasized.

Choose Whole-Grain, High-Fiber Foods
Dietary patterns that are high in whole-grain products and fiber have been associated with increased diet quality. Fiber modestly reduces LDL cholesterol levels, has been associated with decreased CVD risk and slower progression of CVD, and may promote satiety. The AHA recommends that at least half of grain intake come from whole grains.

Consume Fish, Especially Oily Fish, at Least Twice a Week
Fish, especially oily fish, is rich in very long-chain omega-3 polyunsaturated fatty acids: eicosapentaenoic acid, C20:5n-3 (EPA) and docosahexaenoic acid, C22:6n-3 (DHA). The consumption of 2 servings (~8 ounces) per week of fish is associated with a reduced risk of both sudden death and death from coronary artery disease in adults. Methods used to prepare fish should minimize the addition of saturated and trans fatty acids, as occurs with the use of cream sauces or hydrogenated fat during frying.

Limit Your Intake of Saturated and Trans Fat and Cholesterol
As a set of goals, the AHA recommends intakes of <7% of energy as saturated fat, <1% of energy as trans fat, and <300 mg cholesterol per day. These goals can be achieved by choosing lean meats and vegetable alternatives; selecting fat-free (skim), and low-fat (1%-fat), dairy products; and minimizing intake of partially hydrogenated fats. The AHA supports the recommendations of the Institute of Medicine and the National Cholesterol Education Program of 25% to 35% of total energy as fat.

Minimize Your Intake of Beverages and Foods With Added Sugars
Over the past few decades, the consumption of beverages and foods with added sugars has risen markedly. The primary reasons for reducing the intake of beverages and foods with added sugars are to lower total calorie intake and promote nutrient adequacy. Some evidence suggests that calories consumed as liquid are not as satiating as calories consumed as solid food.

Choose and Prepare Foods With Little or No Salt
A reduced sodium intake can prevent hypertension in nonhypertensive individuals, can lower BP in the setting of antihypertensive medication, and can facilitate hypertension control. Because of the progressive dose–response relationship between sodium intake and BP, it is difficult to set a recommended upper level of sodium intake. In view of the available high-sodium food supply and the currently high levels of sodium consumption, the AHA recommends a reduction in sodium intake to 2.3 g/d (100 mmol/d).

If You Consume Alcohol, Do So in Moderation
Moderate alcohol intake has been associated with reduced cardiovascular events in many populations. The consumption of alcohol cannot be recommended solely for CVD risk reduction. Alcohol can be addictive, and high intake can be associated with serious adverse health and social conse-
Plant Stanols/Sterols
Plant stanols/sterols, at levels up to 2 g/d, lower LDL cholesterol levels up to 15%.59,57 and therefore are seen as a therapeutic option, in addition to diet and lifestyle modification, for individuals with elevated LDL cholesterol levels. Plant stanol/sterols are currently available in a wide variety of foods (eg, margarine), drinks (eg, orange juice), and soft gel capsules. The choice of vehicle should be determined by availability and by other considerations, including caloric content. To sustain LDL cholesterol reductions from these products, individuals need to consume them daily, just as they would use lipid-lowering medication.

Special Groups

Children Over 2 Years of Age
Overweight and obesity are a particular concern for children and adolescents. Children can eat a diet consistent with the AHA 2006 Diet and Lifestyle Recommendations and maintain appropriate growth while lowering risk for future CVD.1 More specific guidance is provided in a separate AHA diet statement for children.2

Older Adults
Atherosclerosis is a chronic process beginning in youth. Because of the high incidence of CVD events in older-aged individuals, even relatively small improvements in risk factors (eg, small reductions in BP and LDL cholesterol through diet and lifestyle changes) should be of substantial benefit.58–59

Persons With Metabolic Syndrome
Metabolic syndrome refers to a cluster of abnormalities that are related to insulin resistance and that commonly occur in the setting of overweight and obesity. Refer to a AHA statement specifically addressing the unique issues associated with metabolic syndrome.60

Persons With Chronic Kidney Disease
Chronic kidney disease (CKD), which precedes end-stage kidney disease, substantially increases the risk of CVD.61 Dietary therapies recommended for the general population are also recommended for persons with early stages of CKD, consistent with the individualized guidance provided by the patient’s healthcare provider.62

Socioeconomic Groups at High Risk of CVD
It is well recognized that individuals of lower socioeconomic status have a higher incidence of CVD risk factors and CVD than do individuals of higher socioeconomic status.53,64 Although the reasons for such disparities are complex and multifactorial, available research is sufficient to advocate diet and lifestyle changes as a means to reduce disparities. Targeted messages directed at ethnic minorities and policies that affect availability and affordability are critical.

Environmental Influences on CVD
Health Behaviors
Ultimately, people select the types and amount of food they eat and the amount of physical activity they perform. Still,
environment has a powerful influence on whether people consume excess calories, follow a healthy diet, and are physically active. For individuals to adhere to a healthy diet and lifestyle, the AHA strongly believes that substantial changes to the environment must occur. Key parties in implementing these changes include practitioners, restaur-
ants, food industry, schools and local governments.

Conclusions
A substantial and expanding body of evidence has implicated several aspects of diet and lifestyle in the pathogenesis of CVD and its risk factors. To harness this potential, individuals should aim for a desirable body weight, be physically active. For individuals to adhere to a healthy diet and lifestyle, the AHA strongly believes that substantial environmental changes. The current challenge to healthcare providers, researchers, and government officials is to develop and implement effective clinical and public health strategies that lead to sustained lifestyle changes among individuals and, more broadly, among populations.
